CHANGED  
EVERY  
THING**

**MDG 6: 15 YEARS, 15 LESSONS OF HOPE FROM THE AIDS RESPONSE**

# ANNEXES

## NOTES ON UNAIDS METHODOLOGY

Many of the findings in this report are sourced from the UNAIDS 2014 estimates. These are obtained from country-specific models of their AIDS epidemics. Modelled estimates are required because it is impossible to count the exact number of people living with HIV, people who are newly infected or people who have died of AIDS during the epidemic in any country. To know this for certain would require testing every person for HIV regularly and investigating all deaths, which is logistically impossible and ethically problematic. Below is a brief description of these modelling methods, and further information is available from <http://www.unaids.org/en/dataanalysis/datatools>.

Additional estimates for the years 1990–2014 are available from [www.aidsinfoonline.org](http://www.aidsinfoonline.org).

## PARTNERSHIPS IN CREATING UNAIDS ESTIMATES

Modelled HIV estimates are created by country teams using UNAIDS-supported software. The country teams are comprised primarily of epidemiologists, demographers, monitoring and evaluation specialists and technical partners.

Selected inputs into the model—including the number of people receiving antiretroviral therapy and the number of women accessing prevention of mother-to-child transmission by type of regimen—are reviewed and validated in partnership with the World Health Organization (WHO) and the United Nations Children's Fund (UNICEF). Final country-submitted files containing the modelled outputs are reviewed at UNAIDS to ensure the results are comparable across regions and countries, and over time.

The software used to produce the estimates is Spectrum—developed by the Avenir Health ([www.avenirhealth.org](http://www.avenirhealth.org))—and the Estimates and Projections Package, which is developed by East-West Center (<http://www.eastwestcenter.org/>). The UNAIDS Reference Group on Estimates, Modelling and Projections provides technical guidance on the development of the HIV component of the software ([www.epidem.org](http://www.epidem.org)).

## A BRIEF DESCRIPTION OF METHODS USED BY UNAIDS TO CREATE ESTIMATES

Country teams use UNAIDS-supported software to create national HIV prevalence curves that are consistent with all pertinent, available HIV data in the country. For countries where HIV transmission is high enough to sustain an epidemic in the general population, these data typically consist of HIV prevalence results from surveillance among pregnant women attending antenatal care clinics and from nationally representative population-based surveys. Because antenatal clinic surveillance is performed on a regular basis, these data can be used to inform national prevalence trends, while data from population surveys—which are conducted

less frequently but have broader geographic coverage and also include men—are more useful for informing national HIV prevalence levels. For a small number of countries that have not conducted population surveys, HIV prevalence levels are adjusted based on comparisons of antenatal clinic surveillance and population survey data from other countries in the region. The HIV prevalence curves and numbers receiving antiretroviral therapy are then used to derive an estimate of HIV incidence trends.

Historically, countries with high HIV transmission have produced separate HIV prevalence and incidence trends for rural and urban areas when there are well-established geographic differences in prevalence. To better describe and account for geographic heterogeneity in this report, an increasing number of countries have produced subnational estimates (e.g. at the province or state level) that, in some cases, also account for rural and urban differences. These subnational estimates, or trends in rural and urban areas, are then aggregated to obtain national estimates using Spectrum.

In countries with concentrated or low-level HIV epidemics where HIV transmission is largely contained within key populations at higher-risk of HIV infection (such as people who inject drugs, sex workers or men who have sex with men), repeated HIV prevalence studies are most often used to inform national estimates and trends. Estimates of the size of key populations are increasingly derived empirically in each country or, when studies are not available, based on regional values and consensus among experts. Other data sources—including population surveys, surveillance among pregnant women, and HIV case reporting data—are used to estimate HIV prevalence in the general, low-risk population. The HIV prevalence curves and numbers receiving antiretroviral therapy are then used to derive national HIV incidence trends.

For a select number of countries that have insufficient HIV surveillance or survey data—but which have strong vital registration and disease reporting systems—HIV case reporting and AIDS-related mortality data are used to directly inform trends and levels in national HIV prevalence and incidence. These methods also allow countries to take into account evidence of under-reporting or reporting delays in HIV case report data, as well as the misclassification of deaths due to AIDS.

In countries with high- and low-level HIV epidemics, assumptions about the effectiveness of HIV program scale-up and patterns of HIV transmission and disease progression are used to obtain age- and gender-specific estimates of the number of people living with HIV, the number of new HIV infections, and deaths as well as other important indicators (including program coverage statistics). These assumptions are based on systematic literature reviews and analyses of raw study data by scientific experts. Demographic population data, including fertility estimates, are based on the United Nations Population Division's *World population prospects, 2012 revision*.

## UNCERTAINTY BOUNDS AROUND UNAIDS ESTIMATES

The software calculates uncertainty bounds around all estimates, which can be used to measure how precisely we can speak about the magnitude of the epidemic. These bounds define the range within which the true value lies (if we could measure it).

There are two factors that determine the width of the ranges around the HIV estimates. The first is the quantity and source of the HIV data available; countries with more HIV surveillance data have smaller ranges than countries with less surveillance data or smaller sample sizes. Countries in which a national population-based survey has been conducted will generally have smaller ranges around estimates than countries where such surveys have not been conducted.

The second factor that determines the extent of the ranges around estimates is the number of assumptions required to arrive at the estimate: the more assumptions, the wider the uncertainty range, since each assumption introduces additional uncertainties. For example, ranges around estimates of adult HIV prevalence are smaller than those around estimates of HIV incidence among children (which requires additional data on the probability of mother-to-child HIV transmission). The latter are based on prevalence among pregnant women, the probability of mother-to-child HIV transmission and estimated survival times for HIV-positive children.

Although UNAIDS is confident that the actual numbers of people living with HIV, people who are newly infected or people who have died of AIDS lie within the reported ranges, more and better data from countries will steadily reduce uncertainty.

## IMPROVEMENTS TO THE 2014 UNAIDS ESTIMATES MODEL

Country teams create new Spectrum files every year. Files may differ from one year to the next for two reasons. First, new surveillance and program data are entered into the model; this can change HIV prevalence and incidence trends over time, including for past years. Second, improvements are incorporated into the model based on the latest available science and understanding of the epidemic.

Between the 2013 and 2014 rounds of estimates, the following changes were applied to the model under the guidance of the UNAIDS Reference Group on Estimates, Modelling and Projections and based on the latest scientific evidence:

- In countries with generalized epidemics, an adjustment of the national HIV prevalence trend was made to account for biases in trends based on antenatal clinic sentinel data. These biases were introduced by differential uptake of antiretroviral therapy and changes in the age of infected pregnant women relative to those infected in the general population. This adjustment will result

in lower peaks in HIV prevalence and HIV incidence in these countries, and in general, a slower rate of decline. (1)

- An assumption that women living with HIV who are receiving antiretroviral therapy will have the same fertility rates as HIV-uninfected women of the same age was incorporated. This will result in more women living with HIV becoming pregnant in recent years due to the roll-out of antiretroviral therapy. (2, 3)
- A reduction (from 92% to 70%) was made in the assumed probability of transmitting HIV among those receiving antiretroviral therapy to better capture suboptimal adherence and incomplete HIV viral suppression that have been reported in the literature.
- A new progression model for children infected with HIV based on CD4 count (or CD4 percent for children under the age of 5 years) has replaced the previous child model that relied on a single survival curve. Assumptions for adjusted child mortality rates on antiretroviral therapy by age, sex and CD4 count by region have been developed using data from longitudinal cohort studies prepared for UNAIDS by the IeDEA Consortium.
- HIV transmission probabilities for pregnant women receiving Option B and for those starting antiretroviral therapy during the current pregnancy were reduced based on new data from the PROMISE study. A new transmission probability and regimen was added for women who started antiretroviral therapy during their current pregnancy but fewer than four weeks before delivery. (4)
- Wider use was made of the AIDS Epidemic Model developed by East-West Center and the case reporting and mortality fitting tools in Spectrum in order to construct national prevalence and incidence trends in countries with concentrated epidemics. This will improve the overall accuracy of estimates in these countries.

Because of these improvements to the model and the addition of new data to create the estimates for each year, results from previous years cannot be compared to results from this year. A full historical set of estimates also has been created for this year, allowing for the estimation of trends over time.

## MEASURING ANTIRETROVIRAL COVERAGE

Since 2013, UNAIDS has provided estimates of the proportion of adults and children living with HIV who are receiving antiretroviral therapy (rather than estimates of the proportion of adults and children eligible according to national or international guidelines who are receiving antiretroviral therapy). This change was made because the eligibility criteria for starting antiretroviral therapy vary over time and by country. Note that for most countries, the coverage reported here does not reflect their national antiretroviral therapy guidelines.

## **PUBLICATION OF COUNTRY-SPECIFIC ESTIMATES**

UNAIDS aims to publish estimates for all countries with populations of 250 000 or more. For those countries with populations of 250 000 or more that do not submit estimates, estimates are created by UNAIDS based on published or otherwise available information. These estimates contribute to regional and global totals but are not published.

In countries with concentrated epidemics, the estimated number of pregnant women living with HIV is not easily available. Many women living with HIV in these countries are sex workers, partners of men who have sex with men, or drug users, and thus they are likely to have different fertility levels than the general population. UNAIDS does not present estimates of mother-to-child transmission or estimates related to children infected through mother-to-child transmission in some concentrated epidemic countries unless adequate data are available to validate these estimates.

With regard to monitoring incidence trends, if there is not enough historical data to confidently state whether a decline in incidence has occurred, UNAIDS will not publish earlier data in order to avoid users making inaccurate inferences about trends. Specifically, incidence trends are not published if there are fewer than four data points for the key population, or if there has been no data for the last four years.

Finally, in a few instances, UNAIDS will not publish country estimates when further data or analyses are needed to produce valid estimates. More information on the UNAIDS estimates and the individual Spectrum files for most countries can be found on our website ([www.unaids.org](http://www.unaids.org)).
